KEY CONCEPT

During meiosis, diploid cells undergo two cell divisions that result in haploid cells.

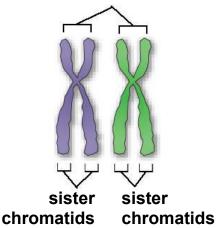

- Cells go through two rounds of division in meiosis.
 - Meiosis reduces chromosome number and creates genetic diversity.

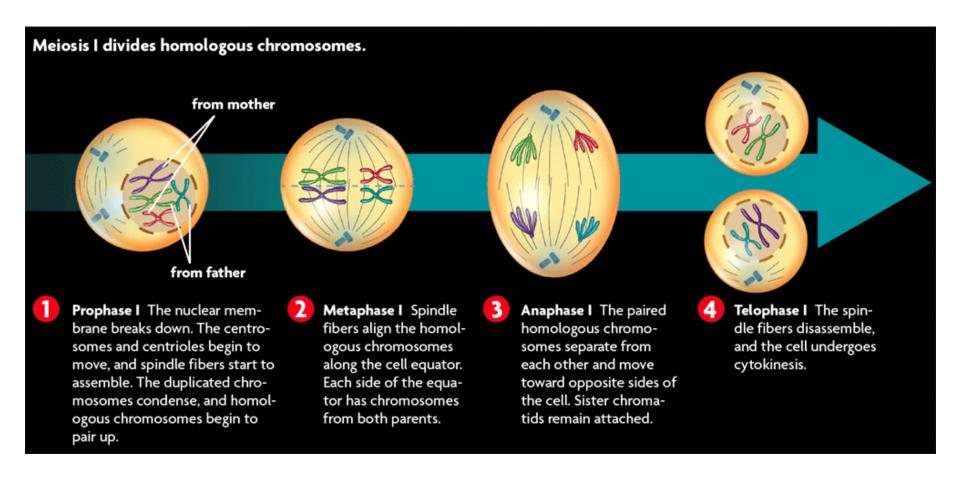

- Meiosis I and meiosis II each have four phases, similar to those in mitosis.
 - Pairs of homologous chromosomes separate in meiosis I.
 - Homologous chromosomes are similar but not identical.
 - Sister chromatids divide in meiosis II.
 - Sister chromatids are copies of the same chromosome.

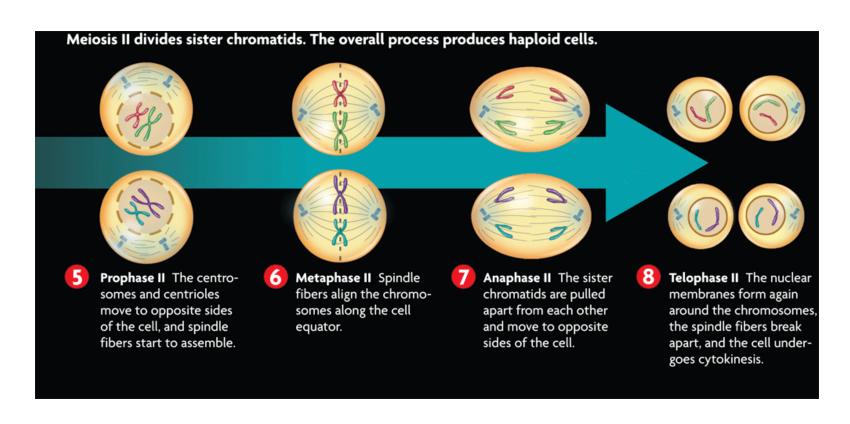

homologous chromosomes

- Meiosis I occurs after DNA has been replicated.
- Meiosis I divides homologous chromosomes in four phases.

- Meiosis II divides sister chromatids in four phases.
- DNA is not replicated between meiosis I and meiosis II.

- Meiosis differs from mitosis in significant ways.
 - Meiosis has two cell divisions while mitosis has one.
 - In mitosis, homologous chromosomes never pair up.
 - Meiosis results in haploid cells; mitosis results in diploid cells.

MITOSIS	
	Produces genetically identical cells
	Results in diploid cells
	Takes place throughout an organism's lifetime
	Involved in asexual reproduction

MEIOSIS	
Produces genetically unique cells	Fux.
Results in haploid cells	
Takes place only at certain times in an organism's life cycle	THE NAME OF THE PARTY OF THE PA
Involved in sexual reproduction	

Haploid cells develop into mature gametes.

- Gametogenesis is the production of gametes.
- Gametogenesis differs between females and males.
 - Sperm become streamlined and motile.
 - Sperm primarily contribute DNA to an embryo.
 - Eggs contribute DNA, cytoplasm, and organelles to an embryo.
 - During meiosis, the egg gets most of the contents; the other cells form polar bodies.
